

ac properties of short Josephson weak links

Andreas Moor¹ and Anatoly F. Volkov¹

¹*Theoretische Physik III, Ruhr-Universität Bochum, D-44780 Bochum, Germany*

(Dated: April 25, 2017)

We calculate the admittance of two types of Josephson weak links—the first is a one-dimensional superconducting wire with a local suppression of the order parameter, and the second is a short S-c-S structure, where S denotes a superconducting reservoir and c is a constriction. The systems of the first type are analyzed on the basis of time-dependent Ginzburg-Landau equations derived by Gor'kov and Eliashberg for gapless superconductors with paramagnetic impurities. It is shown that the impedance $Z(\Omega)$ has a maximum as a function of the frequency Ω , and the electric field E_Ω is determined by two gauge-invariant quantities. One of them is the condensate momentum Q_Ω and another is a potential μ related to charge imbalance. The structures of the second type are studied on the basis of microscopic equations for quasiclassical Green's functions in the Keldysh technique. For short S-c-S contacts (the Thouless energy $E_{Th} = D/L^2 \gg \Delta$) we present a formula for admittance Y valid frequencies Ω and temperatures T less than the Thouless energy E_{Th} ($\hbar\Omega, T \ll E_{Th}$) but arbitrary with respect to the energy gap Δ . It is shown that, at low temperatures, the absorption is absent [$\text{Re}(Y) = 0$] if the frequency does not exceed the energy gap in the center of the constriction ($\Omega < \Delta \cos \varphi_0$, where $2\varphi_0$ is the phase difference between the S reservoirs). The absorption gradually increases with increasing the difference ($\Omega - \Delta \cos \varphi_0$) if $2\varphi_0$ is less than the phase difference $2\varphi_c$ corresponding to the critical Josephson current. In the interval $2\varphi_c < 2\varphi_0 < \pi$, the absorption has a maximum. This interval of the phase difference is achievable in phase-biased Josephson junctions. Close to T_c the admittance has a maximum at low Ω which is described by an analytical formula.

I. INTRODUCTION

The study of dynamic effects in superconductors began soon after the appearance of microscopic BCS theory of superconductivity.¹ Using the BCS theory, Mattis and Bardeen have calculated the admittance of a superconductor $Y(\Omega, q)$.² Later, Abrikosov, Gor'kov and Khalatnikov have obtained the admittance for pure superconductors by using the Green's function technique.³ This technique was applied by Abrikosov and Gor'kov to calculate the linear response of superconductors with impurities.⁴ In more detail, the theory of admittance has been later developed by Nam.⁵ In these papers, it has been shown that at low temperatures absorption is absent if the frequency of electromagnetic field Ω is less than 2Δ . This means that the real part of admittance $\text{Re}[Y(\Omega)] \equiv Y'(\Omega)$ equals zero in the limit $T \rightarrow 0$ and $\Omega < 2\Delta/\hbar$. If frequency Ω exceeds 2Δ , $Y'(\Omega)$ increases with increasing the difference ($\Omega - 2\Delta$).

On the other hand, the intensive study of dynamic collective modes in superconductors, both in low- and high- T_c ones, is carried out in the last decade. A special attention is paid to the amplitude mode (AM), which is called often in literature the Higgs mode.⁶ This mode has been studied theoretically long ago^{7–29}, but only recently it was observed in experiments.^{30,31} A superconductor ($\text{Nb}_{1-x}\text{Ti}_x\text{N}$) was driven out of the equilibrium by a short laser pulse (terahertz frequency range) and the temporal evolution of the deviation $\delta\Delta(t)$ from the equilibrium value Δ was detected by a weak probe signal in picosecond time interval. This evolution can be qualitatively described by the equation⁷

$$\delta\Delta(t) \propto \delta\Delta(0) \frac{\cos(2\Delta t/\hbar)}{\sqrt{2\Delta t/\hbar}}. \quad (1)$$

A weak incident electric field $\mathbf{E}(t) = \mathbf{E}_\Omega \cos(\Omega t)$ obviously can not lead to a perturbation of the order parameter Δ be-

cause it is a scalar so that $\delta\Delta(t)$ can be proportional only to even orders of $\mathbf{E}^{2n}(t)$. However, as we have shown recently,³² the situation changes in the presence of the condensate flow. In this case, even a weak ac field $\mathbf{E}(t)$ leads to a perturbation of Δ , $\delta\Delta_\Omega \propto \mathbf{Q}_\Omega \mathbf{Q}_0$, where $\mathbf{Q}_0 = m\mathbf{v}_0$ is the condensate momentum, \mathbf{v}_0 is the velocity of the condensate, and \mathbf{Q}_Ω is the ac condensate momentum induced by the electric field \mathbf{E}_Ω according to the expression

$$-i\Omega\hbar\mathbf{Q}_\Omega = e\mathbf{E}_\Omega. \quad (2)$$

If the frequency of the external electric field Ω coincides with the frequency of the AM $2\Delta/\hbar$, a resonance absorption of the incident electromagnetic field \mathbf{E}_Ω takes place and the real part $Y'(\Omega) \equiv \text{Re}[Y(\Omega)]$ of admittance has a sharp peak at $\Omega = 2\Delta/\hbar$.

A similar peak was obtained in Ref. 33, where linear response of a superconductor with a finite-momentum pairing was calculated. As the authors of Ref. 33 claim, their results can be applied to high- T_c superconductors with a pair density wave or to superconductors in the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state.^{34,35} In both cases, the superconducting order parameter depends on coordinate, $\Delta(\mathbf{r})$, turning to zero at some points or lines.

High frequency properties of superconductors are important not only from the point of view of fundamental physics, but also of applications. In particular, the use of superconducting devices in qubits and in highly sensitive detectors requires the knowledge of the admittance $Y(\Omega)$.^{36–39} The systems used in practical devices often include Josephson junctions (JJ), for example, S-c-S or S-n-S weak links of different types, where c denotes a constriction and n stands for a normal metal. The study of ac properties of JJs has began long ago (see references in Refs. 40 and 41). The admittance $Y(\Omega)$ of a short JJ of the S-c-S type has been calculated by Artemenko *et al.* on the basis of Keldysh technique for

quasiclassical Green's functions.⁴² It was assumed that the Thouless energy $E_{\text{Th}} = D/L^2$ is much larger than T_c . In particular, it was shown that at low frequencies Ω and close to the critical temperature T_c the admittance has the form [see Eq. (31) in Ref. 42]

$$Y(\Omega) = \frac{2eI_c(v_{\text{in}} + i\Omega)}{\hbar(\Omega^2 + v_{\text{in}}^2)} P(2\varphi_0) + \frac{1}{R}, \quad (3)$$

where $I_c = \pi\Delta^2/(4eTR)$ is the critical current of this JJ near T_c , R is the resistance in the normal state and v_{in} is inelastic scattering time.⁴³ The function $P(2\varphi_0)$ is a function of the phase difference $2\varphi_0$. The form of $P(\varphi_0)$ is displayed in Fig. 5. Equation (3) shows that the reactive part of admittance has a sharp peak at a small frequency $\Omega \approx v_{\text{in}}$ since $v_{\text{in}} \ll \Delta$.

An anomalous behavior of the admittance $Y(\Omega)$ was obtained also in Ref. 44 where also a short JJ was studied by another method (tunnel Hamiltonian method and subsequent averaging via the Dorokhov's procedure).⁴⁵

Lempitski analyzed non-stationary behavior of long ($E_{\text{Th}} \ll \Delta$) S-n-S junctions and has shown that, in this case, inelastic scattering rate also plays an essential role.⁴⁶ Such ac properties of S-n-S JJs as fluctuations of voltage and impedance at currents less than the critical one were analyzed in Ref. 47. The admittance of long S-n-S junctions in the frequency range $\Omega \ll E_{\text{Th}}/\hbar$ has been calculated in recent papers,^{48,49} where an expression for $Y(\Omega)$ similar to Eq. (3) has been obtained. This equation shows an anomalous behavior of the admittance at low frequencies where the maximal value of the admittance is determined by the energy relaxation rate v_{in} .

In the current paper, we calculate and analyze the admittance of short JJs of two configurations. In Section II, we present basic equations for quasiclassical Green's functions which will be used in Section III, where we consider a superconducting wire or film in which the superconducting order parameter Ψ is suppressed locally so that the amplitude $|\Psi(x)|$ has a dip at $x = 0$. At strong suppression, one can speak of a weak link. This model has much in common with the so-called phase-slip centers^{50,51} or FFLO state in superconductors.^{34,35} Far away from the weak point $x = 0$, the ac condensate momentum Q_Ω is connected with an ac field E_Ω via Eq. (2). Near this point, the momentum Q_Ω depends on coordinate, $Q_\Omega(x)$, and the gauge-invariant potential $\mu_\Omega(x)$ related to electron-hole branch imbalance arises.^{52–55} In this case, the electric field is determined both by the gauge-invariant vector \mathbf{Q} and by the gradient of the potential $\nabla\mu_\Omega(x)$ (see, for example, Refs. 55 and 56),

$$\hbar \frac{\partial \mathbf{Q}}{\partial t} = e\mathbf{E} + \nabla\mu. \quad (4)$$

The gauge-invariant quantities \mathbf{Q} and μ are defined in terms of the vector potential \mathbf{A} and scalar electric potential V

$$\mathbf{Q} = \frac{1}{2}(\nabla\chi - 2\pi\mathbf{A}/\Phi_0), \quad (5)$$

$$\mu = \frac{1}{2}(\hbar \frac{\partial \chi}{\partial t} + 2eV), \quad (6)$$

where χ is the phase of the order parameter and $\Phi_0 = hc/2e$ is the magnetic flux quantum. Substituting Eqs. (5) and (6) into Eq. (4), we obtain the standard definition of the electric field \mathbf{E} in terms of potentials \mathbf{A} and V , $\mathbf{E} = -(1/c)\partial_t\mathbf{A} - \nabla V$.

On the basis of time-dependent Ginzburg-Landau equations derived by Gor'kov and Eliashberg for gapless superconductors,⁵⁷ we find both quantities $Q_\Omega(x)$ and $\mu_\Omega(x)$, and calculate the admittance of the system. We will show that the last term at the right is comparable with the first one and therefore can not be neglected as it was done in some papers.

In Section IV we consider a short S-c-S contact. By using a rather general formula for admittance derived in Ref. 42, we analyze the admittance of this JJ. [The authors of Ref. 42 provided the expression Eq. (3) without considering arbitrary frequencies and temperatures.] In this case, the electric field E_Ω is connected with the phase difference φ_Ω in superconducting reservoirs S which are assumed to be in equilibrium. We present the dependence $Y(\Omega)$ for different values of constant phase difference $2\varphi_0$ and arbitrary frequencies. We show that an interesting peculiarity in this dependence arises near the point $\varphi_0 \approx \pi/4$ corresponding to the critical current I_c . Whereas the real part of admittance $Y'(\Omega) = \text{Re}[Y(\Omega)]$ increases smoothly with increasing Ω at $2\varphi_0 < \pi/2$, it has a maximum if the phase difference $2\varphi_0$ exceeds $\pi/2$. Although the latter case corresponds to unstable points on the curve $I_J(\varphi_0)$ in current-biased JJs, it can be realized in phase-biased JJs making the predicted effect observable.^{58,59}

In the Conclusion, we discuss the possibilities to study ac properties of the considered JJs experimentally. Note that a hump in the real part of admittance $Y'(\Omega)$ at high temperatures and low Ω is much broader than the peak in $Y'(\Omega)$ caused by a resonance excitation of the AM in uniform superconductors and is due to another mechanism.³²

II. BASIC EQUATIONS

In this Section, we present basic equations for quasiclassical Green's functions including the Keldysh function which is needed in a non-stationary case. These equations were employed in our previous work for analysis of a uniform case³² and will be used for calculating the admittance of a non-uniform superconductor, i.e., a short S-c-S JJ. We have shown earlier that the AM can be excited even by a weak ac field $\mathbf{E}(t)$ in the presence of a condensate flow. In addition, it was shown that the resonance excitation of the AM contributes to the admittance $Y(\Omega)$ of such a superconductor. Unlike the experiments in terahertz frequency region,^{30,31} the absorption of microwave ac field in superconductors was measured long ago by Martin and Tinkham⁶⁰ and later on by Budzinski *et al.*⁶¹ It was found that a peak near the frequency $\Omega = 2\Delta/\hbar$ arises by applying a magnetic field. The formula describing correctly this peak was obtained by the method of analytical continuation in Ref. 62, the authors of which explained the maximum in the absorption with a singularity in the density of states but did

not relate it with the resonance excitation of the amplitude (Higgs) mode.

Like in Ref. 32, we consider the diffusive limit in one-dimensional geometry so that $\mathbf{Q} = (Q, 0, 0)$. The current \mathbf{I}_Ω and the gap perturbation $\delta\Delta_\Omega$ are found from nonstationary equations for matrix quasiclassical Green's functions \check{g} . These equations, in the absence of a magnetic field, have the form^{55,63–67}

$$-iD\partial_x(\check{g}\partial_x\check{g}) + i(\check{\tau}_3 \cdot \partial_t \check{g} + \partial_{t'} \check{g} \cdot \check{\tau}_3) + [\check{\Sigma}, \check{g}] = V(t)\check{g} - \check{g}V(t'). \quad (7)$$

The diagonal matrix elements of the matrix \check{g} are the retarded (advanced) Green's functions $\hat{g}^{R(A)}$, and the off-diagonal element is the Keldysh function \hat{g} ,

$$\check{g} = \begin{pmatrix} \hat{g}^R & \hat{g} \\ 0 & \hat{g}^A \end{pmatrix}. \quad (8)$$

The functions $\hat{g}^{R(A)}$ and \hat{g} are 2×2 matrices in the particle-hole space. All the functions depend on two times t and t' . The diagonal matrix $\check{\Sigma}$ consists of matrices $\hat{\Sigma}^{R(A)} = \Delta i\hat{\tau}_2 + i\hat{\gamma}^{R(A)}$, where Δ is the superconducting gap and $\hat{\gamma}$ is a damping matrix. The matrix $\check{g}(t, t')$ obeys the normalization condition

$$\check{g} \cdot \check{g} \equiv \int dt_1 \check{g}(t, t_1) \cdot \check{g}(t_1, t') = \check{1} \delta(t - t'). \quad (9)$$

The current in the diffusive limit is determined by the expression

$$\mathbf{I}(t) = -\frac{\pi\sigma}{4e} \int dt_1 \text{Tr} \{ \check{\tau}_3 \check{g}(t, t_1) \nabla \check{g}(t_1, t) \}^K, \quad (10)$$

where σ is the conductivity.

In equilibrium and in absence of a dc current, the Green's functions $\hat{g}^{R(A)}$ and \hat{g} have the form

$$\hat{g}_{\text{eq}}^{R(A)} = [g\hat{\tau}_3 + f i\hat{\tau}_2]^{R(A)}, \quad (11)$$

$$\hat{g}_{\text{eq}} = (\hat{g}^R - \hat{g}^A) \tanh(\epsilon\beta), \quad (12)$$

where $g_{\text{eq}}^{R(A)} = (\epsilon/\Delta)f_{\text{eq}}^{R(A)} = \epsilon/\zeta^{R(A)}(\epsilon)$, $\beta = 1/2T$ and

$$\zeta^{R(A)}(\epsilon) = \sqrt{(\epsilon \pm i\gamma)^2 - \Delta^2}. \quad (13)$$

The matrices $\hat{\tau}_i$ are the Pauli matrices operating in the particle-hole space.

We calculate the impedance and the gauge-invariant quantities Q and μ in the next Section where nonstationary Ginzburg-Landau equations⁵⁷ will be used instead of more complicated Eqs. (7)–(9).

III. SUPERCONDUCTING WIRE WITH A LOCAL GAP SUPPRESSION

We consider a one-dimensional superconducting wire or film in which the superconducting order parameter $\Delta \propto \Psi$

FIG. 1. (Color online.) Schematic view of the system under consideration. (a) The general suppression of the order parameter in a junction and a general setup of a weak link of the length $2L \gg \xi_s$; (b) a short weak link ($2L \ll \xi_s$) with corresponding phases of the order parameters in the superconductors forming the junction.

is locally suppressed, see Fig. 1 (a). Our aim is to calculate the impedance (or admittance) of this system. We describe the system under consideration on the basis of nonstationary Ginzburg-Landau equations that have been derived by Gor'kov and Eliashberg⁵⁷ and were used in many papers. These equations are valid for gapless superconductors with a high concentration of paramagnetic impurities. In the normalized form they have the form

$$\partial_t f = \partial_{xx}^2 f + f[a(x) - f^2] - Q^2 f, \quad (14)$$

$$\nu f^2 \mu = -\partial_x E, \quad (15)$$

$$I = Qf^2 + E, \quad (16)$$

$$\partial_t Q = E + \partial_x \mu. \quad (17)$$

Here, $f = |\Psi|/|\Psi_\infty|$ is the dimensionless modulus of the order parameter Ψ , where $|\Psi_\infty| = \pi\sqrt{(T_c^2 - T^2)}$. The length and time are measured in the units $\xi_{\text{sf}} = \sqrt{12D\tau_0}$ and $t_0 = \hbar^2/(2\tau_{\text{sf}}\Delta^2)$, where τ_{sf} is the spin-flip relaxation time. The current I and the voltage V are measured in units of $\sigma V_0/\xi_{\text{sf}}$ and $V_0 = \hbar/2et_0$. The gauge-invariant quantities Q and μ are defined in Eqs. (5) and (6).

The magnitude of the relaxation rate ν of the normal-

ized potential μ depends on the choice of the model. In the model of a gapless superconductor with paramagnetic impurities considered in Ref. 57 $\nu = 12$. The value of ν in conventional BCS superconductors is much smaller.⁵⁵ The coefficient $a(x)$ describes a suppression of $|\Psi|$, respectively, f . We consider the simplest model when $a(x)$ has the form

$$a(x) = 1 - a_0 \delta(x), \quad (18)$$

where the parameter a_0 can be either small (weak suppression of f) or large (strong suppression of f). The reasons for the suppression of Δ can be different. For example, a locally enhanced concentration of paramagnetic impurities leads to such a suppression. Note that the stationary and non-stationary Josephson effects for large a_0 have been studied in Ref. 68.

From Eq. (18) we find the matching condition

$$2\partial_x f(x)|_{x=0} = a_0 f(0). \quad (19)$$

In this Section, we consider the case when only ac current flows through the system. From Eqs. (14)–(18), one needs to find a spatial dependence $f_0(x)$ in a stationary case and then to determine the linear response to the ac current $I_{ac}(t)$ in the system. Consider first the stationary case.

A. Stationary case

In absence of a constant current ($I_0 = 0$) we need to find a stationary solution only for Eq. (14) complemented by the boundary condition Eq. (19) because the functions Q_0 , μ and E vanish. The solution is

$$f_0(x) = \tanh X \quad (20)$$

with $X = \kappa_0(|x| + x_0)$ and $\kappa_0^2 = 1/2$. The integration constant $X_0 \equiv \kappa_0 x_0$ is found from the matching condition Eq. (19),

$$\sinh(2X_0) = \frac{4\kappa_0}{a_0}. \quad (21)$$

In the case of weak ($a_0 \ll 1$), respectively, strong ($a_0 \gg 1$) suppression, the constant $X_0 = \kappa_0 x_0$ is

$$X_0 = \begin{cases} 2^{-1} \ln(8\kappa_0/a_0), & a_0 \ll 1, \\ 2\kappa_0/a_0, & a_0 \gg 1. \end{cases} \quad (22)$$

The dependence $f_0(x)$ is shown schematically in Fig. 1 (a).

Next, we consider the non-stationary case.

B. Non-stationary case

Having determined the stationary function $f_0(x)$, we can find the linear response, i.e., the functions Q_Ω , μ_Ω and E_Ω in the presence of a weak ac current

$$I_{ac}(t) = I_\Omega \cos(\Omega t). \quad (23)$$

We can linearize Eqs. (14)–(17). Far away from the point $x = 0$, where the normalized order parameter $f(x) \rightarrow 1$, we obtain

$$E_\infty = \frac{-i\Omega}{1-i\Omega} I_\Omega, \quad (24)$$

$$Q_\infty = \frac{1}{1-i\Omega} I_\Omega. \quad (25)$$

Deviations from these values, $\delta E_\Omega = E_\Omega - E_\infty$ and $\delta Q_\Omega = Q_\Omega - Q_\infty$, arise due to a local suppression of superconductivity at $x = 0$. We introduce a function $\mathcal{E}_\Omega(x)$ which is connected with $\delta E_\Omega(x)$ via the relation $\delta E_\Omega = f_0(x)\mathcal{E}_\Omega$. The function \mathcal{E}_Ω obeys the equation (see Appendix A)

$$\left[-\partial_{xx}^2 + \nu(\tanh^2 X - i\Omega) + \frac{1}{\sinh^2 X} \right] \mathcal{E}_\Omega = \frac{-2iI_\Omega\Omega\nu}{(1-i\Omega)\sinh(2X)}. \quad (26)$$

The boundary condition at $x = 0$ for the function \mathcal{E}_Ω is

$$2\partial_x \mathcal{E}_\Omega|_{0+} = -a_0 \mathcal{E}_\Omega(0). \quad (27)$$

We need to solve Eq. (26) and to find an even function $\mathcal{E}_\Omega(x)$ decaying to zero at $x \rightarrow \infty$. The ac voltage δV_Ω across the junction is expressed through \mathcal{E}_Ω via

$$\delta V_\Omega = 2 \int_0^\infty dx f_0(x) \mathcal{E}_\Omega(x). \quad (28)$$

The complex impedance of the system consists of two parts $Z_\Omega = Z_{\Omega L} + \delta Z_\Omega$, where the first term is the impedance in the absence of the weak link ($a_0 = 0$) and the second term is related to the presence of the local suppression

$$Z_{\Omega L} = \frac{-i\Omega}{1-i\Omega} 2L, \quad (29)$$

$$\delta Z_\Omega = \frac{\delta V_\Omega}{I_\Omega}. \quad (30)$$

Note that for small a_0 the problem can be solved analytically. Consider first this case.

1. Weak local suppression

As follows from Eq. (21), for small a_0 we have $\sinh X \simeq \exp[(|x| + x_0)/\sqrt{2}] \gg 1$. In the main approximation, Eq. (26) can be written in the form

$$-\partial_{xx}^2 \mathcal{E}_\Omega + \mathcal{E}_\Omega \kappa_\Omega^2 = -4i\Omega I_\Omega \frac{\nu \exp[-\sqrt{2}(|x| + x_0)]}{1-i\Omega}, \quad (31)$$

where $\kappa_\Omega^2 = \nu(1-i\Omega)$. In the case of a small parameter a_0 , a solution with continuous functions $\mathcal{E}_\Omega(x)$ and $\partial_x \mathcal{E}_\Omega(x)$ is

$$\begin{aligned} \mathcal{E}_\Omega(x) = & \frac{-4ia_0\Omega\nu I_\Omega}{(1-i\Omega)(\kappa_\Omega^2 - 2)} \\ & \times \left[-\frac{\sqrt{2}}{\kappa_\Omega} \exp(-\kappa_\Omega|x|) + \exp(-\sqrt{2}|x|) \right] \exp(-\sqrt{2}|x_0|). \end{aligned} \quad (32)$$

For the voltage δV_Ω and the impedance δZ_Ω we obtain

$$\delta V_\Omega = a_0 \frac{-i\Omega I_\Omega}{(1-i\Omega)^2} \quad (33)$$

and

$$\delta Z_\Omega = a_0 \frac{-i\Omega}{(1-i\Omega)^2}, \quad (34)$$

respectively. Therefore, the impedance variation $\delta Z_\Omega = \delta Z'_\Omega + i\delta Z''_\Omega$ is given by

$$\delta Z'_\Omega \equiv \delta R(\Omega) = a_0 \frac{2\Omega^2}{(1+\Omega^2)^2}, \quad (35)$$

$$\delta Z''_\Omega = -a_0 \frac{\Omega(1-\Omega^2)}{(1+\Omega^2)^2}. \quad (36)$$

The total resistance and the reactive part of the impedance of the wire is

$$R(\Omega) \equiv Z'(\Omega) = \frac{\Omega^2}{(1+\Omega^2)} \left[2L + \frac{2a_0}{(1+\Omega^2)} \right], \quad (37)$$

$$Z''(\Omega) = -\frac{\Omega}{(1+\Omega^2)} \left[2L + \frac{a_0(1-\Omega^2)}{(1+\Omega^2)} \right]. \quad (38)$$

One can see that the active part of the impedance increases due to a suppression of the order parameter f at $x=0$. The reactive part increases at $\Omega \leq 1$ and decreases at $\Omega \geq 1$, that is, the variation of the reactive part $\delta Z''_\Omega$ changes sign at $\Omega = 1$.

It is of interest to find also the admittance $Y(\Omega) \equiv 1/Z(\Omega)$. From Eqs. (30), (35), and (36) in the main approximation in the parameter a_0 , we obtain

$$Y(\Omega) = \frac{1}{2L} \left[1 - \frac{1-a_0/2L}{i\Omega} \right]. \quad (39)$$

This expression shows that the considered system can be modelled as a conductance and an inductance connected in parallel. The small gap suppression causes a small increase in the inductance $\mathcal{L} = 2L/(1-a_0/2L)$ and does not change the real part of the conductance.

2. Strong local suppression

At strong suppression ($a_0 \gg 1$), the solution of Eq. (26), which looks like the ‘‘Schroedinger’’ equation with a complex potential, can be found numerically. In Figs. 2 (a) and 2 (b) we plot the frequency dependence of the changes in the real and imaginary parts of the impedance $\delta Z'_\Omega$ and $\delta Z''_\Omega$ for different values of a_0 . For small a_0 , the results of numerical calculations and the analytical expressions given by Eqs. (35) and (36) coincide.

We see that the resistance due to the weak link $\delta R(\Omega)$ is positive and has a broad maximum at frequencies Ω_m that are slightly less than 1 (at small a_0). The position of the maximum shifts towards smaller Ω_m with increasing a_0 (when a_0 remains less than ≈ 2.5). The reactive

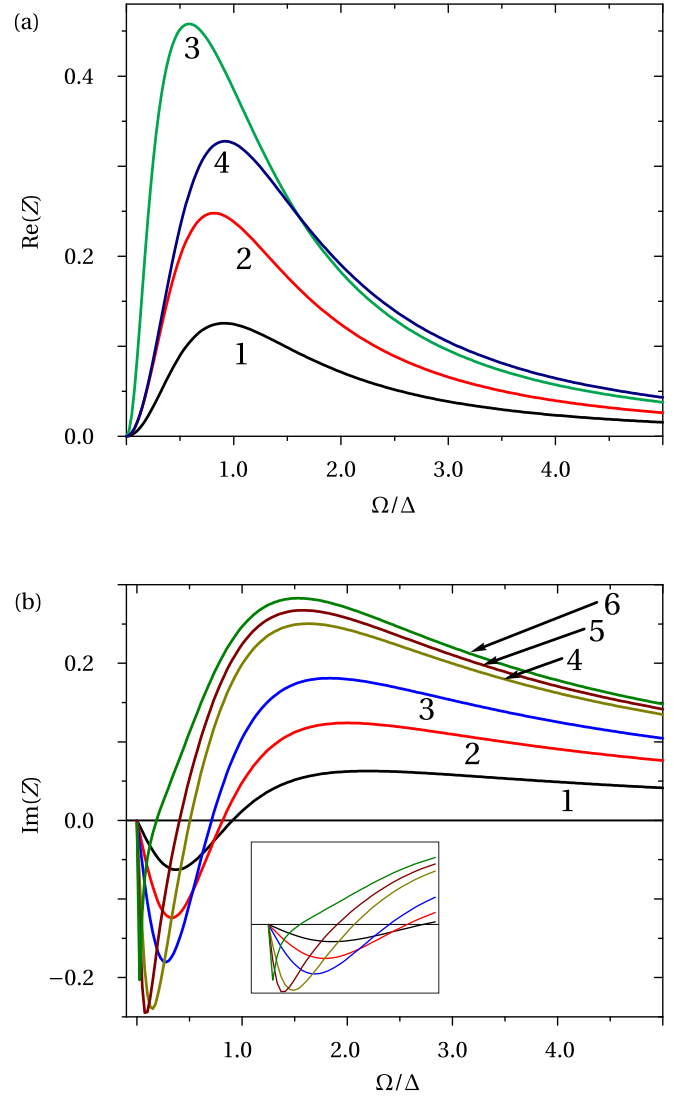

FIG. 2. (Color online.) (a) Frequency dependence of the resistance variation due to a superconductivity suppression. The numbers on the curves denote, correspondingly, the values for a_0 , i.e., (1) $a_0 = 0.5$; (2) $a_0 = 1.0$; (3) $a_0 = 2.0$; (4) $a_0 = 5.0$. (b) Frequency dependence of the variation of the reactive part of impedance due to a superconductivity suppression. The numbers on the curves denote, correspondingly, the values for a_0 , i.e., (1) $a_0 = 0.5$; (2) $a_0 = 1.0$; (3) $a_0 = 2.2$; (4) $a_0 = 2.4$; (5) $a_0 = 2.6$; (6) $a_0 = 2.8$. The inset shows the enlarged part of $\text{Im}(Z)$ at $\Omega \leq \Delta$.

part of the impedance $\delta Z''_\Omega$ changes sign at approximately the same frequencies. At $a_0 \gtrsim 2.5$, the maximum value of $\delta R(\Omega)$ decreases with further increase of a_0 , whereas the frequency Ω_m increases [see Fig. 2 (a)]. The behaviour of the reactive part $\delta Z''_\Omega$ also changes. It is worth noting that in the considered model of a gapless superconductor, the parameter $|\Psi|$ is the amplitude of the superconducting order parameter, but not the gap.

In Figs. 3 (a) and 3 (b) we display the spatial dependence of the dimensionless electric field $\delta E_\Omega(x) = f_0(x)\mathcal{E}_\Omega(x)$ and compare it to the magnitude of the spatial derivative of the

FIG. 3. (Color online.) Frequency dependence of the electric field variation $\delta E_\Omega(x) = f_0(x)\mathcal{E}_\Omega(x)$ and the derivative $\partial_x \mu_\Omega(x)$ as well as their ratio for (a) $a_0 = 0.5$; (b) $a_0 = 2.4$. In both cases, the frequency $\Omega = 0.8\Delta$. All quantities are correspondingly normalized, see Eqs. (14)–(17).

gauge-invariant potential $\partial_x \mu_\Omega(x)$ for two values of a_0 , i.e., for $a_0 = 0.5$ (weak suppression) and $a_0 = 2.4$ (strong suppression). One can see that these quantities may be comparable in their values. This means that the electric field \mathbf{E}_Ω is not determined only by the condensate momentum \mathbf{Q}_Ω [see Eq. (2) which is valid in a uniform case] and that in order to find the linear response of a superconductor with a non-homogeneous order parameter $f(x)$, the potential $\mu_\Omega(x)$ has to be calculated also alongside with \mathbf{Q}_Ω if the ac electric field \mathbf{E}_Ω is directed parallel to x axis. This statement is true, for instance, for the case of the FFLO state (compare it with Ref. 33, where the optical conductance of a non-homogeneous superconductor was calculated in the gauge with $\mathbf{A} \neq 0$ and $V = 0$ so that $\mu = 0$).

IV. S-C-S CONTACT

In this Section, we consider short Josephson junctions of the S-c-S or S-n-S types in the dirty limit, i.e., in the limit $\tau T_c \ll 1$, where τ is the momentum relaxation time. We also assume that there are no barriers at the S-c interfaces. In the considered model, two superconducting reservoirs S are connected by a narrow constriction. Since the length of the constriction $2L$ is assumed to be less than the coherence length $\xi_S \approx \sqrt{D/T_c}$, that is, the Thouless energy is large ($D/L^2 \gg T_c$), it does not matter whether the constriction is normal or superconducting.

Formula for the impedance $Z(\Omega)$ in this case has been obtained by one of the authors (in collaboration with Artemenko and Zaitsev) in 1979⁴² on the basis of microscopic theory of the Josephson effects in these JJs, but it has not been analyzed in detail. Here, we reproduce the main steps of the derivation of this expression, correct typos in Ref. 42 and analyze the admittance of the short S-c-S JJs in more detail. [The signs in Eq. (29) of Ref. 42 should be changed in such a way that expressions in the curly brackets in Eqs. (27) and (29) coincide with each other if the functions $g^A(\epsilon_-)$ in Eq. (27) are replaced by $g^R(\epsilon_-)$. The imaginary unit i in front of the right-hand side of Eq. (29) has to be dropped. The last term in Eq. (31) should have the form $\hbar i \omega \varphi_\omega / 2eR$. Note that ω in Ref. 42 corresponds to $-\Omega$.] Note that the admittance of a similar S-c-S contact has been calculated and analyzed in a recent paper,⁴⁴ where another model and method of calculations were used.

The microscopic theory developed in Ref. 42 is based on the generalized Usadel equation, Eq. (7), which describes the spatial dependence of the Green's functions $\check{g}(x, t, t')$ in the constriction. These functions are assumed to be continuous at the S-c and c-S interfaces (no potential barriers at these interfaces).

In the considered limit of a short junction, one can neglect all the terms in Eq. (7) except the first one and we obtain for the “anisotropic” part

$$\check{a} = -l \check{g} \partial_x \check{g} = \text{const.} \quad (40)$$

That is, the matrix \check{a} does not depend on the coordinate x . The current I through the considered JJ is expressed through the anisotropic part of the Keldysh function \hat{a} as follows

$$I(t) = -\frac{\pi\sigma}{4e} \int dt_1 \text{Tr} \{ \hat{\tau}_3 \hat{g} \partial_x \hat{g} \}^K. \quad (41)$$

A formal solution of Eq. (40) is (for brevity we drop the temporal indices t and t')

$$\check{g}(x) = \check{g}(0) \exp(-\check{a}x/l). \quad (42)$$

As follows from Eq. (9), the matrices \check{a} and $\check{g}(0)$ anticommute and $\check{g}(0) \cdot \check{g}(0) = \hat{1}$. Thus, introducing the matrices $\check{G}^{(\pm)} \equiv [\check{G}(L) \pm \check{G}(-L)]/2$ and using Eq. (42), we obtain

$$\check{G}^{(+)} = \check{g}(0) \cosh(\check{a}L/l), \quad (43)$$

$$\check{G}^{(-)} = \check{g}(0) \sinh(\check{a}L/l), \quad (44)$$

where $\check{G}(\pm L) \equiv \check{G}^{(\pm)}$ are the known matrix Green's functions in the reservoirs. From this equation we find

$$\check{a} = -\frac{l}{2L} \operatorname{arsinh}[2\check{G}^{(+)} \cdot \check{G}^{(-)}]. \quad (45)$$

In particular,

$$\hat{a}^{R(A)} = -(l/2L) \operatorname{arsinh}[2\hat{G}^{(+)} \cdot \hat{G}^{(-)}]^{R(A)}. \quad (46)$$

The matrices $[\hat{g}^{(\pm)}]^{R(A)}$ are expressed in terms of the retarded (advanced) Green's functions in the reservoirs $\hat{g}^{R(A)}(\pm L) \equiv \hat{G}^{R(A)}$ that are known and have the form

$$\hat{G}^{R(A)}(\pm L) = \hat{S}(t, \pm L) \cdot \hat{G}_0^{R(A)}(t - t') \cdot \hat{S}^\dagger(t', \pm L). \quad (47)$$

Here, we introduce the transformation matrix $\hat{S}(t, \pm L) = \exp(i\hat{\tau}_3\varphi(t, \pm L)/2)$ in order to take into account the presence of the phase of the superconducting order parameter in the banks $\varphi(t, \pm L) = \pm[\varphi_0 + \varphi_{ac}(t)]$. The Green's functions $\hat{G}_0^{R(A)}(\epsilon)$ in reservoirs in the absence of phase difference coincide with the matrices $\hat{g}_{eq}^{R(A)}$ defined in Eq. (11).

Consider first the stationary case.

A. Stationary case

In the equilibrium case [$\varphi_{ac}(t) = 0$], the Keldysh function \hat{a} depends only on the time difference $(t - t')$ and its Fourier component is

$$\hat{a}(\epsilon) = [\hat{a}_0^R(\epsilon) - \hat{a}_0^A(\epsilon)] \tanh(\epsilon\beta), \quad (48)$$

where $\beta = 1/2T$. The matrices $\hat{a}^{R(A)}(\epsilon)$ are found from Eqs. (46) and (47),

$$\hat{a}_0^{R(A)}(\epsilon) = -\frac{l}{L} [\Delta \cos \varphi_0 \hat{\tau}_3 + \epsilon i \hat{\tau}_2] b^{R(A)}(\epsilon) \quad (49)$$

with

$$b^R(\epsilon) = \frac{i}{\check{\zeta}^R(\epsilon)} \operatorname{arsinh}\left[\frac{\Delta \sin \varphi_0}{\check{\zeta}^R(\epsilon)}\right] \quad (50)$$

and $\check{\zeta}^R(\epsilon) = \sqrt{(\epsilon + i\gamma)^2 - \Delta^2 \cos^2 \varphi_0}$. The function $\check{\zeta}^R(\epsilon)$ is defined in Eq. (13).

In obtaining Eq. (49), we used the relation

$$\operatorname{arsinh}\left[\frac{2\Delta\check{\zeta}^R(\epsilon) \sin \varphi_0}{[\check{\zeta}^R(\epsilon)]^2}\right] = 2\operatorname{arsinh}\left[\frac{\Delta \sin \varphi_0}{\check{\zeta}^R(\epsilon)}\right], \quad (51)$$

and the expressions for $\{\hat{G}^{(+)}\}^{R(A)}$ and $\{\hat{G}^{(-)}\}^{R(A)}$, which directly follow from Eq. (47),

$$\{\hat{G}^{(+)}\}^{R(A)} = \{G(\epsilon) \hat{\tau}_3 + F(\epsilon) i \hat{\tau}_2 \cos \varphi_0\}^{R(A)}, \quad (52)$$

$$\{\hat{G}^{(-)}\}^{R(A)} = \{F(\epsilon) i \hat{\tau}_1 \sin \varphi_0\}^{R(A)}. \quad (53)$$

Thus, the Josephson dc current I_J can be easily found from Eqs. (41) and (48). The integration over energy ϵ can

be transformed to the summation over Matsubara frequencies $\omega > 0$ for the first term in Eq. (48) and over negative ω for the second term. As a result we obtain

$$I_J = I_c(\varphi_0) \sin(2\varphi_0), \quad (54)$$

where the critical current I_c also depends on the phase difference $2\varphi_0$ and is determined by the expression⁴³

$$I_c(\varphi_0) = \frac{2\pi T}{eR} \sum_{\omega>0} \frac{\Delta}{\check{\zeta}_\omega(\varphi_0) \sin \varphi_0} \arcsin\left(\frac{\Delta \sin \varphi_0}{\check{\zeta}_\omega}\right), \quad (55)$$

where $R^{-1} = \sigma \mathcal{S}/2L$ with the cross section area of the junction \mathcal{S} .

One can see that near T_c , when $\arcsin(\Delta \sin \varphi_0 / \check{\zeta}_\omega) \simeq \Delta \sin \varphi_0 / \omega$ and $\check{\zeta}_\omega(\varphi_0) \simeq \omega$, the critical current does not depend on the phase difference $2\varphi_0$ and is equal to $I_c = (\pi/4)(\Delta^2/eTR)$.⁴³ At low temperatures, the phase dependence of the Josephson current deviates from the sinusoidal one.

B. Non-stationary case

In this Section, we find a linear response of the system to ac phase variation φ_Ω . To do this, we need to find a deviation of the Keldysh component $\delta \hat{a} = \hat{a} - \hat{a}_0$ due to variation φ_Ω . It can be written in the form

$$\delta \hat{a} = \delta \hat{a}^R \tanh(\epsilon_- \beta) - \tanh(\epsilon_+ \beta) \delta \hat{a}^A + \hat{a}^{\text{an}}. \quad (56)$$

The first two terms represent a regular part, which is an analytical function in the upper (lower) half-plane, and the last term is a non-analytical “anomalous” part.^{55,57}

Therefore, the current I through the S-c-S JJ can be written in the form

$$I_\Omega = I_\Omega^{\text{reg}} + I_\Omega^{\text{an}}, \quad (57)$$

where

$$I_\Omega^{\text{reg}} = \frac{\varphi_\Omega}{8eR} \int d\bar{\epsilon} [j^R(\epsilon_+, \epsilon_-) \tanh(\epsilon_- \beta) - \tanh(\epsilon_+ \beta) j^A(\epsilon_+, \epsilon_-)] \quad (58)$$

and

$$I_\Omega^{\text{an}} = \frac{\varphi_\Omega}{8eR} \int d\bar{\epsilon} j^{\text{an}}(\epsilon_+, \epsilon_-) [\tanh(\epsilon_- \beta) - \tanh(\epsilon_+ \beta)]. \quad (59)$$

The functions j^R and $j^{\text{an}}(\epsilon)$ are determined as follows (see Appendix B)

$$j^R(\epsilon_+, \epsilon_-) = \frac{[b(\epsilon_+)[(G_+ - G_-)\epsilon_+ - (F_+ + F_-)\Delta \cos^2 \varphi_0]]^R}{[F(\epsilon_+) - F(\epsilon_-) \sin \varphi_0]^R} + \frac{[b(\epsilon_-)[(G(\epsilon_+) - G(\epsilon_-))\epsilon_- + (F_+ + F_-)\Delta \cos^2 \varphi_0]]^R}{[F(\epsilon_+) - F(\epsilon_-) \sin \varphi_0]^R}, \quad (60)$$

$$j^{\text{an}} = \frac{b^R(\epsilon_+)[(G_+^R - G_-^A)\epsilon_+ - (F_+^R + F_-^A)\Delta \cos^2 \varphi_0]}{[F^R(\epsilon_+) - F^A(\epsilon_-) \sin \varphi_0]} + \frac{b^A(\epsilon_-)[(G_+^R - G_-^A)\epsilon_- + (F_+^R + F_-^A)\Delta \cos^2 \varphi_0]}{[F^R(\epsilon_+) - F^A(\epsilon_-) \sin \varphi_0]}. \quad (61)$$

Equations (57)–(61) together with the Josephson relation (we assume the equilibrium state in the S reservoirs),

$$V_\Omega = (\hbar/2e)(-i\Omega)\varphi_\Omega, \quad (62)$$

determine the admittance of the system $Y_\Omega = I_\Omega/V_\Omega$.

One can see that at low frequencies and temperatures $\text{Re}[Y(\Omega)]$ is zero. Indeed, one can represent $\tanh(\epsilon_\pm\beta)$ in the form $\tanh(\epsilon_\pm\beta) \simeq \tanh(\bar{\epsilon}\beta) \pm (\Omega/2) \cosh^{-2}(\bar{\epsilon}\beta)$. Taking into account that at $|\bar{\epsilon}| \leq \Delta \cos(\varphi_0)$ $\tilde{\zeta}^R = \tilde{\zeta}^A = i\sqrt{\tilde{\Delta}^2 - \epsilon^2}$ and $\zeta^R = \zeta^A = i\sqrt{\Delta^2 - \epsilon^2}$ coincide, we obtain that $G^R = G^A$ and $F^R = F^A$. This means that the part of the regular “currents” $-(j^R + j^A)(\Omega/2) \cosh^{-2}(\bar{\epsilon}\beta)$ cancels the anomalous “current” $j^{\text{an}}(\Omega/2) \cosh^{-2}(\bar{\epsilon}\beta)$. The remaining part of the regular “current”, $(j^R - j^A) \tanh(\bar{\epsilon}\beta)$, contribute only to the imaginary part of the admittance $\text{Im}[Y(\Omega)]$.

In Fig. 4 (a) we displayed the frequency dependence of the product $Y'(\Omega)\Omega$ (where Ω is normalized to 2Δ) which is proportional to the kernel $Q(\Omega)$ in Fig. 8 of Ref. 4, where the kernel Q has been calculated for a uniform dirty superconductor.

In Fig. 4 (b), we present the frequency dependence of the real part of admittance $Y'(\Omega)$ (normalized to its value in the normal state) at low temperatures for various values of the phase difference $2\varphi_0$. One can see that $Y'(\Omega)$ increases with increasing Ω if the frequency Ω exceeds a threshold value Ω_{Th} which depends on φ_0 . In the absence of the phase difference (no supercurrent flows through the JJ) we have $\Omega_{\text{Th}} = 2\Delta/\hbar$. The curves correspond to $\cos(2\varphi_0) = 1$ (red), $\cos(2\varphi_0) = 0.87$ (black), $\cos(2\varphi_0) = 1/\sqrt{2}$ (green), and $\cos(2\varphi_0) = 0$ (blue). At low temperatures, the real part of the admittance $Y'(\Omega)$ increases monotonously with increasing Ω if the latter exceeds 2Δ and $\varphi_0 \leq \varphi_c$, where φ_c is the phase difference corresponding to critical current. At $\varphi_0 > \varphi_c$, the admittance has a maximum at small Ω .

As we noted in the Introduction, an interesting behavior of the admittance takes place at low Ω and high temperatures ($T \gg \Delta$). The main contribution to the real part $Y'(\Omega)$ [see Eq. (57)] stems from j^{an} . Integration over large energies ϵ ($\epsilon \gg \Delta$) gives the second term $1/R$ at the right hand side of Eq. (3). In this case, $F^R(\epsilon_+) \simeq -F^A(\epsilon_-) \simeq \Delta/\epsilon$, $G^R(\epsilon_+) \simeq -G^A(\epsilon_-) \simeq 1$, and $b^R \simeq b^A \simeq i\Delta \sin \varphi_0/\epsilon^2$. The largest contribution occurs due to the first terms in the square brackets in Eq. (61). Integrating these terms,

$$\begin{aligned} I_{1\Omega}^{\text{an}} &= \frac{i\varphi_\Omega}{4eR} \int d\bar{\epsilon} [\tanh(\epsilon_+\beta) - \tanh(\epsilon_-\beta)] \\ &\simeq \frac{i\Omega\varphi_\Omega}{2eR} \int_0^\infty d\bar{\epsilon} \cosh^{-2}(\bar{\epsilon}\beta) = \frac{V_\Omega}{R}, \end{aligned} \quad (63)$$

we obtain the main contribution to the the admittance $1/R$.

The second important contribution to $Y'(\Omega)$ stems from the second term in the square brackets at the right hand side of Eq. (61) in the energy interval

$$\tilde{\Delta} = \Delta \cos \varphi_0 \leq \epsilon \leq \Delta. \quad (64)$$

In this interval, we have $F^R(\epsilon_+) - F^A(\epsilon_-) \simeq (\Omega/2 + i\nu_{\text{in}})\partial_\epsilon F^R$, $\tilde{\zeta}^R = -\tilde{\zeta}^A$ and $\text{arsinh}(\frac{\Delta \sin \varphi_0}{\tilde{\zeta}^R}) + \text{arsinh}(\frac{\Delta \sin \varphi_0}{\tilde{\zeta}^A}) = -i\pi$. There-

FIG. 4. (Color online.) (a) Frequency dependence of the product $Y'(\Omega) \cdot \Omega$ which corresponds to the kernel $Q(\Omega)$ in Fig. 8 of Ref. 4. (b) Frequency dependence of the real part of admittance $Y'(\Omega)$ at low temperatures for various values of the phase difference $2\varphi_0$. One can see that $Y'(\Omega)$ increases with increasing Ω if the frequency Ω exceeds a threshold value Ω_{Th} which depends on φ_0 . In the absence of the phase difference (no supercurrent flows through the JJ) we have $\Omega_{\text{Th}} = 2\Delta/\hbar$. The curves correspond to $\cos(2\varphi_0) = 1$ (red), $\cos(2\varphi_0) = 0.87$ (black), $\cos(2\varphi_0) = 1/\sqrt{2}$ (green), and $\cos(2\varphi_0) = 0$ (blue). At low temperatures, the real part of the admittance $Y'(\Omega)$ increases monotonously with increasing Ω if the latter exceeds 2Δ and $\varphi_0 \leq \varphi_c$, where φ_c is the phase difference corresponding to critical current. At $\varphi_0 > \varphi_c$, the admittance has a maximum at small Ω .

FIG. 5. (Color online.) The form of the function of $P(\varphi_0)$.

fore, setting $\cosh^{-2}(\epsilon\beta) \approx 1$, we obtain at $T \gg \Delta$

$$I_{2\Omega}^{\text{an}} = \frac{2eV_{\Omega}}{\hbar} \frac{\pi\Delta^2}{2T} \frac{\gamma_{\epsilon} - i\Omega \cos^2 \varphi_0}{\gamma_{\epsilon}^2 + \Omega^2} \frac{1}{\sin \varphi_0} \int_{\cos \varphi_0}^1 dx \frac{1-x^2}{x\sqrt{x^2 - \cos^2 \varphi_0}} \quad (65)$$

$$= \frac{2eV_{\Omega}}{\hbar} I_c \frac{\gamma_{\epsilon} - i\Omega}{\gamma_{\epsilon}^2 + \Omega^2} P(\varphi_0),$$

where $v_{\text{in}} = \gamma_{\epsilon}/2$. Thus, the admittance is given by Eq. (3) with the function $P(\varphi_0)$ equal to

$$P(\varphi_0) = \cot(\varphi_0)[2\varphi_0 - \sin(2\varphi_0)]. \quad (66)$$

The function $P(\varphi_0)$ is shown in Fig. 5.

The integral in Eq. (63) can be calculated for any temperatures if the factor $\cosh^{-2}(\epsilon\beta)$ in the integrand is taken into account, i.e., not using the approximation $\cosh^{-2}(\epsilon\beta) \approx 1$.

Therefore, the deviation $\delta Y'(\Omega)$ of the real part of the admittance $Y'(\Omega)$ from its value in the normal state ($1/R$) is

$$\delta Y'(\Omega)R = \frac{2eI_c R}{\hbar} \frac{\gamma_{\epsilon}}{\gamma_{\epsilon}^2 + \Omega^2} P(\varphi_0). \quad (67)$$

The normalized deviation $\delta \tilde{Y}'(\Omega) \equiv \delta Y'(\Omega)R$ has a maximum at $\Omega = 0$ with a magnitude $\delta \tilde{Y}'(\Omega)_{\text{max}} \approx 2eI_c R / \hbar v_{\text{in}} \approx \Delta^2 / (T \hbar v_{\text{in}})$ which can be much larger than 1. The enhancement of the admittance, Eq. (67), is caused by quasiparticles with energies in the interval defined by Eq. (64).

It is of interest to calculate the density of states (DOS) $N(\epsilon, x)$ in the junction and its spatial dependence. Note that this dependence cannot be found in tunnel Hamiltonian approach. The function $N(\epsilon, x)$ is zero at energies $|\epsilon| \leq \tilde{\Delta}$, but is finite at energies $|\epsilon| \geq \tilde{\Delta}$. In this energy range, $\tilde{\Delta} \leq |\epsilon| \leq \Delta$, the DOS $N_{<}(\epsilon, x)$ is given by (see Appendix C and Ref. 69)

$$N_{<}(\epsilon, x) = \frac{|\epsilon|}{\sqrt{\epsilon^2 - \tilde{\Delta}^2}} \cosh(\tilde{x} \ln M_{<}) \cos\left(\frac{\pi}{2} \tilde{x}\right), \quad (68)$$

where the function $M_{<}$ is

$$M_{<} = \frac{\Delta \sin \varphi_0 + \sqrt{\epsilon^2 - \Delta^2} \cos^2 \varphi_0}{\sqrt{\Delta^2 - \epsilon^2}}. \quad (69)$$

FIG. 6. (Color online.) Density of states as a function of the coordinate $\tilde{x} = x/L$: (a) for $\cos(\varphi_0) < E < 1$ with the curves corresponding to the values $E = 0.51$ (long-dashed orange) and $E = 0.9$ (solid green); (b) for $E > 1$ with the curves corresponding to the values $E = 1.05$ (long-dashed red) and $E = 1.9$ (solid blue). The short-dashed black curve denotes in both cases the value $N = 1$. We set $\cos \varphi_0 = 0.5$.

FIG. 7. (Color online.) Density of states as a function of the normalized energy $E = \epsilon/\Delta$ for different values of the coordinate $\tilde{x} = x/L$, i.e., $\tilde{x} = 0$ (solid red), $\tilde{x} = 0.5$ (dashed blue), and $\tilde{x} = 0.9$ (dash-dotted green). We set $\cos \varphi_0 = 0.5$.

We plot the DOS $N_{<}(\epsilon, x)$ for different $E \equiv \epsilon/\Delta$ in Fig. 6 (a). As it should be, at $x = \pm L$, the DOS turns to zero. At energies ϵ below the gap $\tilde{\Delta}$ ($|\epsilon| \leq \tilde{\Delta}$) in the center of the junction the DOS is also zero. Above the gap Δ ($|\epsilon| \geq \Delta$) the DOS is

$$N_{>}(\epsilon, x) = \frac{|\epsilon|}{\sqrt{\epsilon^2 - \tilde{\Delta}^2}} \cosh(\tilde{x} \ln M_{>}), \quad (70)$$

where

$$M_{>} = \frac{\Delta \sin \varphi_0 + \sqrt{\epsilon^2 - \Delta^2 \cos^2 \varphi_0}}{\sqrt{\epsilon^2 - \Delta^2}}. \quad (71)$$

The DOS $N_{>}(\epsilon, x)$ for different E is shown in Fig. 6 (b).

In Fig. 7 we plot the dependence of the DOS on the energy $E \equiv \epsilon/\Delta$ for different values of \tilde{x} . In a ballistic case, the function $N(\epsilon)$ has sharp peaks at energies corresponding to the positions of Andreev's levels. In the considered diffusive case these peaks are smeared out by impurity scattering so that the dependence $N(\epsilon)$ is a smooth curve having singularities at the edges, $\epsilon = \Delta \cos \varphi_0$ and $\epsilon = \Delta$.

V. CONCLUSIONS

We analyzed the admittance $Y(\Omega)$ of short weak links of two types. The first one is a one-dimensional superconducting wire with a local suppression of the superconducting order parameter $|\Psi|$. This system resembles a phase-slip center or a one-dimensional Larkin-Ovchinnikov-Fulde-Ferrell structure. We calculated Y and the impedance $Z = Y^{-1}$ on the basis of non-stationary Ginzburg-Landau equations.⁵⁷ Ac current through this wire induces a condensate momentum Q_Ω and an inhomogeneity of $|\Psi|$ leads to branch imbalance n_{imb} and to the appearance of another gauge-invariant quantity, the potential μ , proportional to n_{imb} .

As we mentioned in the Introduction, the branch-imbalance, i.e., the unequal population of the electron- and hole-like branches of the excitation spectrum, arises in nonuniform superconductors when a conversion of the supercurrent j_S into the quasiparticle current j_N takes place (see Refs. 52–55). The typical examples of such a conversion are the passage of the charge current through the S/N boundary,^{54,70,71} or collective phase mode, i.e., Carlson-Goldman mode,⁷² in uniform superconductors.^{55,73–75} In the latter case, nonuniform perturbations of the the currents j_N and j_S propagate with a finite wave vector k converting into each other so that the total current density $j = j_N + j_S$ is not perturbed, $j = 0$.

The electric field E , which arises in the wire (see Fig. 1), is caused by both quantities, Q_Ω and $\partial_x \mu$ so that neither of these quantities can be neglected (compare with a recent paper, Ref. 33, where only the quantity $\mathbf{Q} \propto \mathbf{A}$ was taken into account). The real part of the impedance Z' has a maximum at some frequency Ω_m which decreases with increasing suppression of $|\Psi|$.

We also analyzed ac properties of short Josephson S-c-S weak links. The admittance $Y(\Omega)$ is described by an expression that has been obtained on the basis of microscopic equations for quasiclassical Green's function in the Keldysh technique.⁴² The obtained dependence $Y(\Omega)$ is valid in a wide range of the frequencies Ω and temperatures T provided the Thouless energy $E_{\text{Th}} = D/L^2$ exceeds Δ , T , and $\hbar\Omega$.

At low temperatures T , the absorption is absent ($Y' = 0$) if the energy of photons $\hbar\Omega$ is less than the lowest energy gap

in the center of the constriction $\tilde{\Delta} = \Delta \cos \varphi_0$. With increasing the difference $(\hbar\Omega - \tilde{\Delta})$, the absorption monotonously increases if the phase difference $2\varphi_0$ is less than the phase difference $2\varphi_c$ corresponding to a maximum of the Josephson current $I_J = I_c$. In the interval $2\varphi_c < 2\varphi_0 < \pi$, the dependence of $Y'(\Omega)$ has a maximum.

The hump in the obtained dependence $Y'(\Omega)$ is much broader than the peak in absorption in a current-carrying superconductor.³² The mechanisms causing these maxima are different. In the first case, the maximum stems from excitation of quasiparticles with energy range defined by Eq. (64). These quasiparticles are bound in a potential well within the constriction. In the second case, in Ref. 32, the peak is related to a resonance excitation of the Higgs mode by an ac field.

The anomalous enhancement of the real part of the admittance $Y'(\Omega)$ at low frequencies Ω described by Eq. (67), is caused by interference of Cooper pairs and quasiparticles with energies in the interval determined by Eq. (64). These quasiparticles experience multiple Andreev reflections. In the ballistic case, the quasiparticles occupy Andreev's levels.^{76–78} In the diffusive case, these levels are broadened by impurity scattering^{44,79} so that the peaks in the DOS $N(\epsilon, x)$ corresponding to Andreev's levels disappear, and the function $N(\epsilon, x)$ is a smooth function with singularities at $\epsilon = \Delta \cos \varphi_0$ and $\epsilon = \Delta$. In the latter case, anomalous behaviour of low energy quasiparticles results in a singularity of dc conductance at $V \rightarrow 0$.⁷⁹

The enhancement of $Y'(\Omega)$ at low frequencies results in an enhancement of the supercurrent noise because the real part of admittance and spectral function of noise are connected by the fluctuation-dissipation theorem. The anomalous noise in Josephson weak links has been studied in detail in many papers.^{80–85}

Note an important circumstance. In a current-biased S-c-S JJ, the states with phase difference $2\varphi_c < 2\varphi_0$ are unstable, so that it is impossible to observe a non-monotonous dependence of absorption in these junctions. However, in recent experiments^{58,59} it was shown that the phase difference $2\varphi_0$ in the interval

$$2\varphi_c < 2\varphi_0 < \pi \quad (72)$$

is reachable. Thus, it would be interesting to observe a non-monotonous dependence of absorption in such JJs by appropriate adjustment of the phase difference $2\varphi_0$ with the help of an external magnetic field. In these experiments, the S-c-S Josephson weak link was incorporated into a superconducting loop. The phase difference is determined by a magnetic field H_0 through this loop,

$$2\varphi_0 = 2\pi \left(n + \frac{\Phi}{\Phi_0} \right), \quad (73)$$

where $\Phi = H_0 S + \mathcal{L} I_J$ is the magnetic flux through the loop, and S respectively \mathcal{L} are the area respectively inductance of the loop.

Therefore, the absorption can be studied in the setup used in Ref. 59 if the magnetic field contains not only dc

but also an ac component, $H(t) = H_0 + H_\Omega \cos(\Omega t)$. Qualitatively, our results are applicable to the system studied in Ref. 59 because the length of the constriction $2L$ ($2L \approx 160\text{nm}$) is comparable with the coherence length $\xi_S \approx 100\text{nm}$. By varying H_0 , one can change the phase φ_0 using the relation in Eq. (73) and study the absorption of the ac component $H_\Omega \cos(\Omega t)$ as a function of the frequency Ω .

At high temperatures ($T \gg \Delta$), the main contribution to the admittance Y_Ω occurs due to the anomalous term. Quasiparticles with large enough energies ($\epsilon \geq \Delta$) yield the admittance Y' approximately equal to that in the normal state $Y'_n = 1/R$, whereas quasiparticles with energy range defined by Eq. (64) lead to an enhanced admittance $\delta Y'$ at low Ω which can exceed Y'_n by $\Delta/\gamma_{\text{in}}$ times. The dependence of $\delta Y'$ on dc current (or phase difference) is described by an analytical expression, Eq. (67).

ACKNOWLEDGMENTS

We are grateful to Valeri V. Pavlovskii for his kind support by numerical calculations.

Appendix A: Ginzburg-Landau equation

Linearizing Eqs. (14)–(17) we obtain the set of equations for the function δE_Ω ,

$$v f_0^2(x) \mu_\Omega = -\partial_x \delta E_\Omega, \quad (\text{A1})$$

$$\delta Q_\Omega f_0^2(x) + Q_\infty [f_0^2(x) - 1] = -\delta E_\Omega, \quad (\text{A2})$$

$$-i\Omega \delta Q_\Omega = \delta E_\Omega + \partial_x \mu_\Omega. \quad (\text{A3})$$

Excluding δQ_Ω and μ_Ω , we get

$$\delta E_\Omega v [f_0^2(x) - i\Omega] - \left[\partial_{xx}^2 \delta E_\Omega - 2 \frac{\partial_x f_0(x)}{f_0(x)} \partial_x \delta E_\Omega \right] = -i\Omega Q_\infty v [1 - f_0^2(x)]. \quad (\text{A4})$$

One can exclude the first derivative $\partial_x \delta E_\Omega$ via the trans-

formation $\delta E_\Omega = f_0(x) \mathcal{E}_\Omega$. Thus, an “effective electric field” \mathcal{E}_Ω satisfies the equation

$$-\partial_{xx}^2 \mathcal{E}_\Omega + \mathcal{E}_\Omega \left[v(f_0^2(x) - i\Omega) + 2 \left(\frac{\partial_x f_0(x)}{f_0(x)} \right)^2 - \frac{\partial_{xx}^2 f_0(x)}{f_0(x)} \right] = -i\Omega I_\Omega \frac{v[1 - f_0^2(x)]}{f_0(x)[1 - i\Omega]}. \quad (\text{A5})$$

Using the expression Eq. (20) for $f_0(x)$, we obtain Eq. (26).

At $x = 0$, the function \mathcal{E}_Ω is continuous, while $\partial_x \mathcal{E}_\Omega$ has a jump. It can be found directly from Eq. (19)

$$\begin{aligned} [\partial_x \mathcal{E}_\Omega] &= 2\partial_x \mathcal{E}_\Omega|_{0+} \\ &= -\frac{\partial_x f_0(x)}{f_0(0)} \mathcal{E}_\Omega(x)|_{x=0} \\ &= -a_0 \mathcal{E}_\Omega(0), \end{aligned} \quad (\text{A6})$$

where $[\partial_x \mathcal{E}_\Omega] \equiv \partial_x (\mathcal{E}_\Omega|_{x=0+} - \mathcal{E}_\Omega|_{x=0-})$, see also Eq. (27).

Appendix B: Expression for the current

In the first step, it is necessary to find the functions $\delta \hat{a}^{R(A)}$. From the normalization condition Eq. (9) we get

$$[\hat{a} \cdot \hat{g} + \hat{g} \cdot \hat{a}]^{R(A)} = 0. \quad (\text{B1})$$

Linearizing this equation, we obtain for deviations caused by the ac perturbation of the phase φ_Ω

$$[\delta \hat{a} \cdot \hat{g} + \hat{g} \cdot \delta \hat{a}]^{R(A)} = -[\hat{a}_0 \cdot \delta \hat{g} + \delta \hat{g} \cdot \hat{a}_0]^{R(A)}, \quad (\text{B2})$$

where the matrices $\hat{a}_0^{R(A)}$ are determined by Eq. (49). We took into account that neither \hat{a}_0 nor $\delta \hat{a}$ do not depend on the coordinate x . Then, we subtract Eq. (B2) from itself taken at different points $x = \pm L$,

$$[\delta \hat{a} \cdot \hat{G}_\varphi^{(-)} + \hat{G}_\varphi^{(-)} \cdot \delta \hat{a}]^{R(A)} = -[\hat{a}_0 \cdot \delta \hat{G}^{(-)} + \delta \hat{G}^{(-)} \cdot \hat{a}_0]^{R(A)}. \quad (\text{B3})$$

The matrix $\hat{G}_\varphi^{(-)}$ is defined as

$$\hat{G}_\varphi^{(-)} = [\hat{G}_\varphi(L) - \hat{G}_\varphi(-L)]^{R(A)} / 2 \quad (\text{B4})$$

with $\hat{G}_\varphi^{R(A)}(\pm L) = [G(\epsilon) \hat{\tau}_3 + F(\epsilon) i(\hat{\tau}_2 \cos \varphi_0 \pm \hat{\tau}_1 \sin \varphi_0)]^{R(A)}$, and, thus, the matrix $\hat{G}^{(-)}$ is given by Eq. (53).

The deviation $\delta\hat{G}^{(-)}$ due to a small phase perturba-

tions φ_Ω is found from Eq. (47),

$$\begin{aligned}\delta\hat{G}^{(-)} &= \delta[(1 + i\hat{\tau}_3\varphi_\Omega)\hat{G}_{\text{st}}^{(-)}(1 - i\hat{\tau}_3\varphi_\Omega)] \\ &= \varphi_\Omega i[-\hat{\tau}_0(G_+ - G_-) + \hat{\tau}_1(F_+ + F_-)\cos\varphi_0],\end{aligned}\quad (\text{B5})$$

where $G_\pm \equiv G_0(\epsilon_\pm)$, $\epsilon_\pm = \bar{\epsilon} \pm \Omega/2$. As follows from Eq. (41), we need to find $\text{Tr}\{\hat{\tau}_3\hat{a}\}$. Thus, multiplying Eq. (56) by $i\hat{\tau}_2$ and calculating the trace, we find

$$\frac{1}{2}\text{Tr}\{\hat{\tau}_3\hat{a}\}^{R(A)} = \frac{l\varphi_\Omega\{(b_+\epsilon_+ + b_-\epsilon_-)(G_+ - G_-) - \Delta\cos^2\varphi_0(F_+ + F_-)(b_+ - b_-)\}^{R(A)}}{L(F_+ - F_-)^{R(A)}\sin\varphi_0}.\quad (\text{B6})$$

The same equation holds for $\text{Tr}\{\hat{\tau}_3\hat{a}^{\text{an}}\}$ if all functions like G_-^R in Eq. (B4) for \hat{a}^R are replaced by G_-^A .

Appendix C: Density of states in an S-c-S type contact

The density of states is determined by the expression

$$N(\epsilon) = \frac{1}{4}\text{Tr}\{\hat{\tau}_3(\hat{g}^R(\epsilon, x) - \hat{g}^A(\epsilon, x))\},\quad (\text{C1})$$

where $\hat{g}^{R(A)}(\epsilon, x)$ are determined by Eq. (42) which can be written in the form (dropping the indices $R(A)$)

$$\hat{g}(\epsilon, x) = \hat{g}(\epsilon, 0)[\cosh[l^{-1}x\hat{a}(\epsilon)] - \sinh[l^{-1}x\hat{a}(\epsilon)]],\quad (\text{C2})$$

where the functions $\cosh[l^{-1}x\hat{a}(\epsilon)]$ and $\sinh[l^{-1}x\hat{a}(\epsilon)]$ can be presented as follows

$$\cosh[l^{-1}x\hat{a}(\epsilon)] = \cosh\left(\frac{x}{L}A\right),\quad (\text{C3})$$

$$\sinh[l^{-1}x\hat{a}(\epsilon)] = \frac{\hat{m}}{i\tilde{\zeta}(\epsilon)}\sinh\left(\frac{x}{L}A\right),\quad (\text{C4})$$

where we defined $A = \text{arsinh}[\zeta^{-1}(\epsilon)\Delta\sin\varphi_0] = \ln M$ with $M = \zeta^{-1}(\epsilon)[\Delta\sin\varphi_0 + \tilde{\zeta}(\epsilon)]$, and $\hat{m} = \tilde{\Delta}\hat{\tau}_3 + \epsilon i\hat{\tau}_2$. We used the expression for the matrix \hat{a} from Ref. 42,

$$\hat{a} = -\frac{il}{L\tilde{\zeta}(\epsilon)}\hat{m}A.\quad (\text{C5})$$

The matrix $\hat{g}(\epsilon, 0)$ is found from Eq. (44),

$$\hat{g}(\epsilon, 0) = \frac{\hat{G}^{(+)}}{\cosh A}.\quad (\text{C6})$$

Therefore, Eq. (C2) can be written in the form

$$\hat{g}(\epsilon, x) = \frac{\hat{G}_+}{\cosh A}\left[\cosh(\tilde{x}A) + \frac{\hat{m}}{i\tilde{\zeta}(\epsilon)}\sinh(\tilde{x}A)\right].\quad (\text{C7})$$

Using Eq. (C1) we obtain for the density of states

$$N(\epsilon, x) = \frac{1}{2}\left\{\left[g(\epsilon)\frac{\cosh(\tilde{x}\ln M)}{\cosh(\ln M)}\right]^R - \left[g(\epsilon)\frac{\cosh(\tilde{x}\ln M)}{\cosh(\ln M)}\right]^A\right\}.\quad (\text{C8})$$

One can easily show that $\cosh(\ln M) = \tilde{\zeta}(\epsilon)\zeta^{-1}(\epsilon)$. Therefore, the density of states $N(\epsilon, x)$ for $|\epsilon| \geq \Delta$ when $\tilde{\zeta}^R(\epsilon) = -\tilde{\zeta}^A(\epsilon)$ can be written as follows

$$N(\epsilon, x) = \frac{|\epsilon|}{2\tilde{\zeta}(\epsilon)}\left\{\left[\cosh(\tilde{x}\ln M)\right]^R + \left[\cosh(\tilde{x}\ln M)\right]^A\right\}.\quad (\text{C9})$$

Consider two cases:

1. $|\epsilon| \geq \Delta$. In this case, $M^R = [M^A]^{-1} \equiv M_>$, where $M_> = \zeta_>^{-1}(\epsilon)[\Delta\sin\varphi_0 + \tilde{\zeta}_>(\epsilon)]$ with $\tilde{\zeta}_>(\epsilon) = \sqrt{\epsilon^2 - \tilde{\Delta}^2}$, and $\zeta_>(\epsilon) = \sqrt{\epsilon^2 - \Delta^2}$. We obtain

$$\begin{aligned}N(\epsilon, x) &= \frac{|\epsilon|}{\tilde{\zeta}(\epsilon)}\cosh(\tilde{x}\ln M_>) \\ &= \frac{|\epsilon|}{2\tilde{\zeta}(\epsilon)}[M_>^{\tilde{x}} + M_>^{-\tilde{x}}].\end{aligned}\quad (\text{C10})$$

2. $\tilde{\Delta} \leq |\epsilon| \leq \Delta$. In this case, $M^R = -i\zeta_<^{-1}(\epsilon)[\Delta\sin\varphi_0 + \tilde{\zeta}_>(\epsilon)] \equiv -iM_<$ and $M^A = -i\zeta_<^{-1}(\epsilon)[\Delta\sin\varphi_0 - \tilde{\zeta}_>(\epsilon)]$, and one can write the sum in Eq. (C9) in the form

$$[\cosh(\tilde{x} \ln M)]^R + [\cosh(\tilde{x} \ln M)]^A = 2 \cosh \left[\frac{\tilde{x}}{2} (M^R + M^A) \right] \cosh \left[\frac{\tilde{x}}{2} (M^R - M^A) \right] \quad (\text{C11})$$

$$= 2 \cos \left(\frac{\pi \tilde{x}}{2} \right) \cosh [\tilde{x} \ln M_<]. \quad (\text{C12})$$

Combining Eqs. (C9)–(C11) we obtain Eq. (68).
